This hard-back Dover book "The Absolute Differential Calculus: Calculus of Tensors" (ISBN 978-0-486-44637-0) is of limited value now, and I think that the \$70 RRP is a bit excessive, but it is interesting to see how DG was understood when it was more a branch of classical analysis than a branch of geometry or topology. The title indicates clearly the old way of thinking, namely that DG was a branch of calculus (i.e. classical analysis).

The absolute differential calculus (calculus of tensors) Levi-Civita T. A chief requirement in the study of relativity is absolute differential calculus, which Einstein used to mathematically develop his ideas. This classic was written by a founder in the field, offering a clear, detailed exposition.

In mathematics, Ricci calculus constitutes the rules of index notation and manipulation for tensors and tensor fields in a Riemannian manifold. It is

also the modern name for what used to be called the absolute differential calculus, developed by Gregorio Ricci-Curbastro in 1887–1896, and subsequently popularized in a paper written with his pupil Tullio Levi-Civita in 1900. Jan Arnoldus Schouten developed the modern notation and formalism for this mathematical framework, and made ...

$h = 3 + 14t - 5t^2$. and came up with this derivative: $h' = 0 + 14 - 5(2t) = 14 - 10t$. Which tells us the slope of the function at any time t . We used these Derivative Rules: The slope of a constant value (like 3) is 0. The slope of a line like $2x$ is 2, so $14t$ has a slope of 14.

~~Finding Maxima and Minima using Derivatives~~

If $f(c) \leq f(x)$ for all values of the domain, then $f(c)$ is the absolute minimum of the function. If $f(c) \geq f(x)$ for all values of the domain, then $f(c)$ is the absolute maximum of the function. Take note that an extrema is absolute if the value of $f(c)$ is the highest/lowest for all possible $f(x)$.
